# REST

The screenshot displays a REST client interface with a dark theme. At the top, the request method is **POST** and the URL is **http://localhost:5000/greeting**. A **Send** button is visible. The response status is **200 OK**, with a response time of **3.39 ms** and a response size of **28 B**. Below the status bar, there are tabs for **JSON**, **Auth**, **Query**, **Headers** (with a count of 1), and **Doc**. The **JSON** tab is selected, showing the request body as a JSON object: 

```
1 {  
2   "greeting": "Hello World!"  
3 }
```

. To the right, there are tabs for **Preview**, **Headers** (with a count of 5), and **Cookies**. The **Preview** tab is selected, showing the response body as a JSON object: 

```
1 {  
2   "greeting": "Hello World!"  
3 }
```

# GraphQL Features

# Single Endpoint

## REST

```
# Typical routes in Flask REST apps
```

```
app = Flask(__name__)
```

```
app.add_url_rule('/greeting',  
view_func=GreetingView.as_view('greeting'))
```

```
app.add_url_rule('/goodbye',  
view_func=GoodByeView.as_view('goodbye'))
```

```
@app.route('/welcome', methods=['GET'])  
def welcome():  
    ...
```

## GraphQL

```
# Route in Flask GraphQL apps
```

```
app = Flask(__name__)
```

```
app.add_url_rule(  
    "/graphql",  
    view_func=GraphQLView.as_view("graphql_view",  
        schema=schema),  
)
```

# Operations

## REST

**GET:** Fetch data

**POST, PUT, PATCH,**

**DELETE:** Add, edit, modify and delete operations

## GraphQL

HTTP Method used is **POST** always.

**QUERY:** Fetch data

**MUTATION:** Modify, update, delete, etc.

**SUBSCRIPTION:** Realtime persistent operations

# Strong Typing

POST ▼ http://localhost:5000/graphql Send ▼

GraphQL ▼ Auth ▼ Query Headers <sup>1</sup> Docs

Operations schema 

```
1 mutation {  
2   updateGreeting {  
3     message  
4     name  
5   }  
6 }  
7
```

Field "updateGreeting" argument "greeting" of type "String!" is required, but it was not provided.

updateGreetingGreeting!

# Scalars & Types in GraphQL

- **Int**      A signed 32-bit integer.
- **Float**    A signed double-precision floating-point value.
- **String**    A UTF-8 character sequence.
- **Boolean**        true or false.
- **ID**    The ID scalar type represents a unique identifier

Other types/containers: **List**, **NonNull**, **Enum**, **Union**, **Interface**

# Scalars & Types in GraphQL

## Enumeration

```
enum Episode {  
  NEWHOPE  
  
  EMPIRE  
  
  JEDI  
}
```

## Custom type

```
type Character {  
  name: String!  
  
  appearsIn: [Episode]!  
}
```

## Union type

```
union SearchResult =  
  Human | Droid | Starship
```

# Advantages of GraphQL

# Overfetching Prevention

## Initial API Version

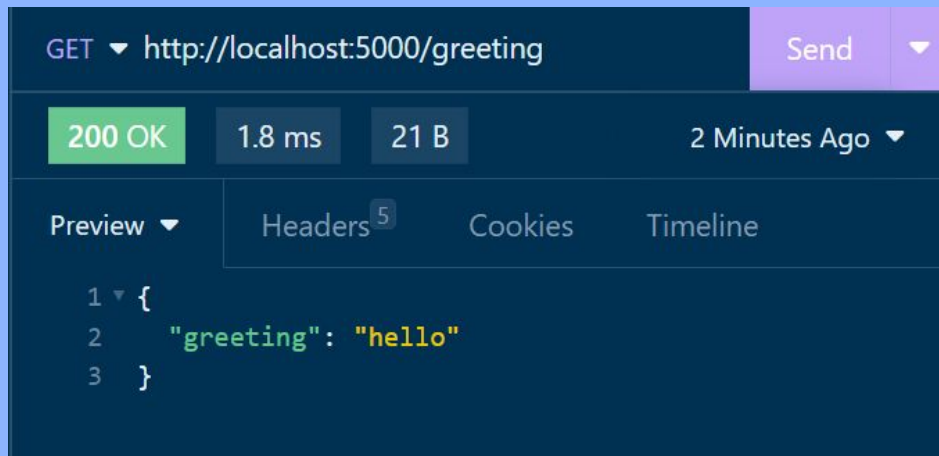

Return a greeting message

## New Requirement

For desktop web clients, return a greeting image along with the greeting message

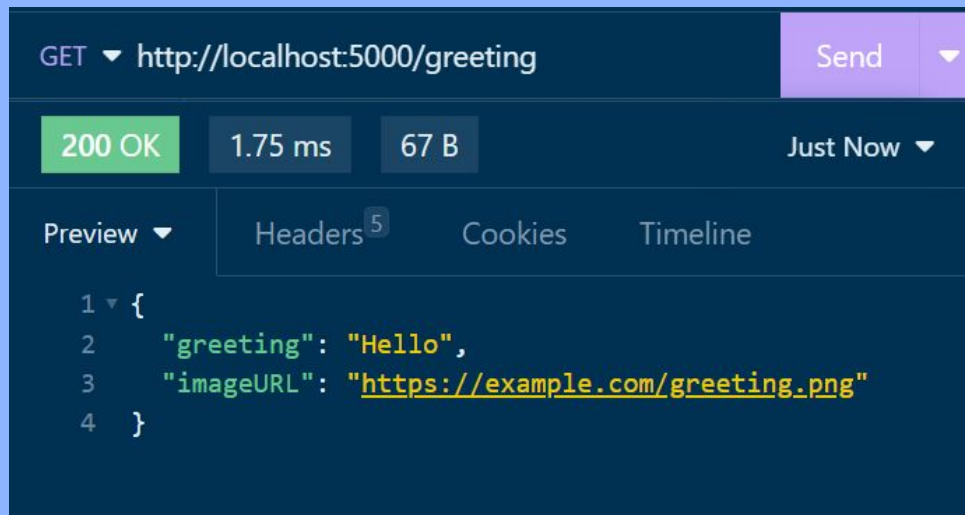

# Overfetching Prevention

## REST - Initial Version

# Overfetching Prevention

## REST - Option 1

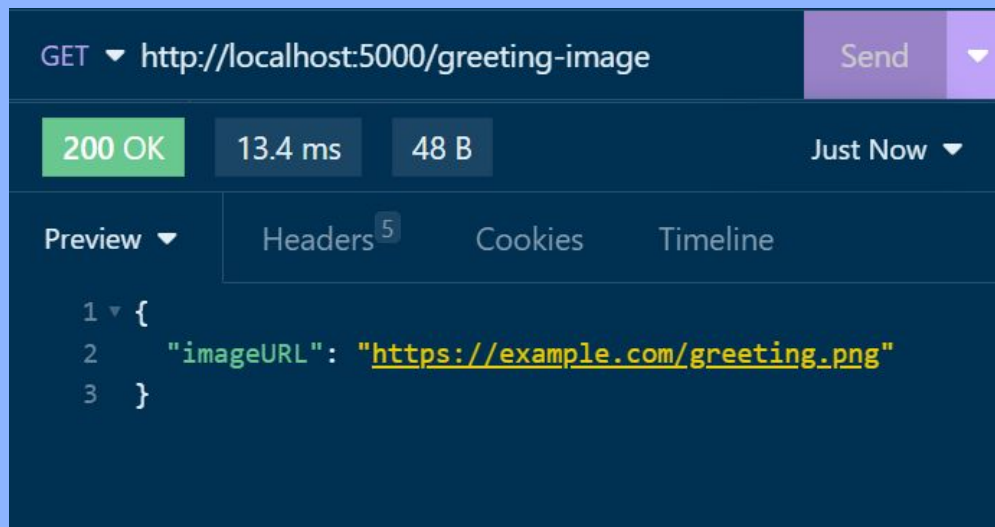

Disadvantage: For mobile clients, an extra unused field is returned with the response

# Overfetching Prevention

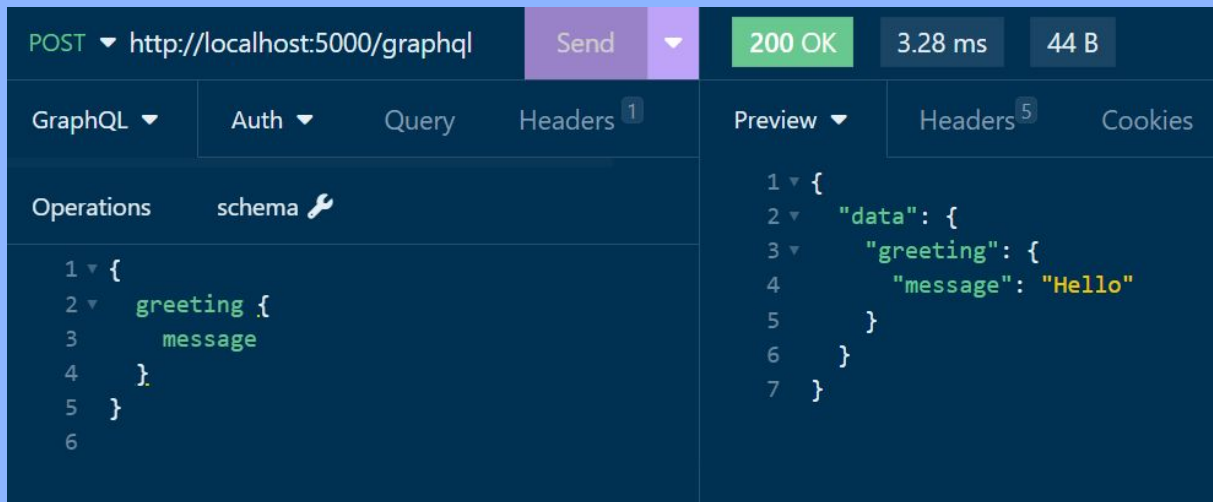

## REST - Option 2 - Adding separate endpoint

Disadvantage: Extra network call and complexity for web clients

# Overfetching Prevention

## GraphQL Solution

The screenshot displays a GraphQL client interface with a dark theme. At the top, a status bar shows a POST request to `http://localhost:5000/graphql` with a 'Send' button, a '200 OK' status, a response time of '3.28 ms', and a size of '44 B'. Below this, there are tabs for 'GraphQL', 'Auth', 'Query', and 'Headers'. The 'GraphQL' tab is active, showing a query editor with a schema icon. The query is: 

```
1 {  
2   greeting {  
3     message  
4   }  
5 }  
6
```

 To the right of the query editor, there are tabs for 'Preview', 'Headers', and 'Cookies'. The 'Preview' tab is active, showing the JSON response: 

```
1 {  
2   "data": {  
3     "greeting": {  
4       "message": "Hello"  
5     }  
6   }  
7 }
```

Query of Mobile client

# Overfetching Prevention

## GraphQL Solution - Desktop client

GraphQL allows us to query only the fields we need

# Introspection & Type system

- Strongly typed and schema based
- All supported operations by a server are returned by 'introspection'
- Presence of tooling to auto generate client code
- REST would require additional doc tools - 'flasgger' or 'flask-rest-api'.
- GraphQL development is centered around its schema

# Choosing a GraphQL Server

# Schema First vs Code First

## Schema First

```
from ariadne import QueryType, make_executable_schema

# Ariadne - GraphQL schema definition as Python string
type_defs = """
type User {
  id: ID!
  name: String!
}

type Query {
  getUser(id: ID!): User
}
"""

query = QueryType()

@query.field("getUser")
def resolve_get_user(_, info, id):
    return {"id": id, "name": "John Doe"}

schema = make_executable_schema(type_defs, query)
```

## Code First

```
import graphene

# Graphene - Schema expressed using
# Python objects
class User(graphene.ObjectType):
    id = graphene.ID(required=True)
    name = graphene.String(required=True)

class Query(graphene.ObjectType):
    get_user = graphene.Field(User,
    id=graphene.ID(required=True))

    def resolve_get_user(root, info, id):
        return User(id=id, name="John
Doe")

schema = graphene.Schema(query=Query)
```

Demo

# GraphQL Federation

# Apollo Federation

- A standard/spec for combining multiple independent GraphQL schemas
- Combines multiple related schemas from microservices (subgraphs) to a single unified schema (supergraph)
- Abstracts away the microservice design from clients

# When to use GraphQL & Federation

- Use GraphQL where it shines - Example: internal APIs with diverse use cases
- Use GraphQL Federation when it fits your architecture / when a monolith becomes unmanageable

[ From "[8 Years of GraphQL: Unraveling the Trade-Offs](#)" Talk by Marc-Andre Giroux (GraphQL Conf 2023) ]

# Federation - Concepts

# Directives

A directive decorates part of a GraphQL schema or operation with additional configuration. Denoted using '@' - similar to decorators in Python

POST http://localhost:5001/graphql Send 200 OK 9.15 ms 82 B

# Entity

- An Entity in Federation is an object type that can resolve its fields across multiple subgraphs.
- It can be thought of as a GraphQL type which appears across multiple microservice subgraphs.

# Entity - UserType

# @key directive

- Designates an object type as an entity.
- The @key directive is used to indicate fields that can be used to uniquely identify and fetch an object.

```
@strawberry.federation.type(keys=["id"])  
class UserType:  
    id: strawberry.ID  
    username: str  
    email: str
```

# Federation Gateway/Router

- Combines multiple microservice schemas and exposes a single combined endpoint
- Intelligent - It holds the logic to resolve entities and shared types

# Reference resolver function

The reference resolver function enables the Federation gateway's query planner to resolve a particular entity by its @key fields.

```
@strawberry.federation.type(keys=["id"])
class UserType:
    id: strawberry.ID
    username: str
    email: str

    @classmethod
    def resolve_reference(cls, id: strawberry.ID):
        with Session() as session:
            user = session.query(User).get(int(id))
            return UserType(id=user.id, username=user.username,
                             email=user.email)
```
